## **Supplementary Information**

## Appendix A

### Nomenclature and use of equilibrium constants

#### Case 1. Non-leveled acid dissociation

Consider a non-leveled acid, HA, that partially dissociates according to the equilibrium presented in Eq. S1:

HA represents a generic monoprotic acid dissociating into its Brønsted conjugate base,  $A^-$ , and hydronium ion,  $H_3O^+$ . For practical purposes, this species is denoted as  $H^+$ . Thus, the apparent acidity constant for this acid is written according to Eq. S2.

$$K_a = \frac{[H^+][A^-]}{[HA]} \quad \text{Eq. S2}$$

By reversing the direction of the equilibrium reaction presented in Eq. S1, the equilibrium of Eq. S3, which corresponds to the formation of such acid.

The nomenclature to designate the apparent global formation constant of the previous equilibrium is  $\beta_{1,1}^{A^-|H^+}$ . The superscripts indicate the polyreceptor and the exchanged particle, separated by the character pleca ( $|$ ), in the context of the equilibrium of Eq. S3, the polyreceptor is  $A^-$ , and the exchanged particle is  $H^+$ . On the other hand, the subscripts indicate the reaction's stoichiometry, that is, the number of polyreceptors and particles necessary to form the product. The arrangement of these numbers corresponds to the position mentioned in the superscript. Thus,  $1A^-$  and  $1H^+$  are required to form HA. The apparent global formation constant of the HA acid (presented in Eq. S3), formed from the chemical entity  $A^-$  with exchanged  $H^+$ , is defined based on Eq. S4.

$$\beta_{1,1}^{A^-|H^+} = \frac{[HA]}{[A^-][H^+]} \quad \text{Eq. S4}$$

This nomenclature has been used in other works, allowing the identification and manipulation of equilibrium constants in systems that involve polynuclear chemical entities and systems in the presence of condensed phases (Guerash-Briones et al. 2023).

The apparent global formation constant,  $\beta_{1,1}^{A^-|H^+}$ , is inversely proportional to the acidity constant,  $K_a$  (associated with the same equilibrium, but presented in opposite directions). The relationship between these constants is indicated in Eq. S5.

$$\beta_{1,1}^{A^-|H^+} = \frac{1}{K_a} \quad \text{Eq. S5}$$

Finally, by applying logarithms on both sides, it is established that the logarithm of the apparent global formation constant,  $\beta_{1,1}^{A^-|H^+}$ , is equal to the  $pK_a$  of the acid–base pair HA/ $A^-$ ; according to the first and last members of Eq. S6.

$$\log \beta_{1,1}^{A^-|H^+} = \log \frac{1}{K_a} = -\log K_a = pK_a \quad \text{Eq. S6}$$

**Case 2. Dissociation of water**

Autoprotolysis is called the chemical equilibrium in which water molecules are present to produce hydronium and hydroxide ions, according to the equilibrium presented in Eq. S7.

The autoionization constant is expressed as follows:

$$K_w = [H^+][OH^-] \quad \text{Eq. S8}$$

The chemical equilibrium of Eq. S7 in the opposite direction will correspond to the global formation constant of water,  $\beta_{1,1}^{OH^-|H^+}$ , returning to the nomenclature presented previously. The expression of the law of mass action is expressed in Eq. S9.

$$\beta_{1,1}^{OH^-|H^+} = \frac{1}{[H^+][OH^-]} \quad \text{Eq. S9}$$

The interdependence presented in Eq. S5 can be applied to the water system, where the overall formation constant of water formation,  $\beta_{1,1}^{OH^-|H^+}$ , is inversely proportional to the autoprotolysis constant Eq. S10.

$$\beta_{1,1}^{OH^-|H^+} = \frac{1}{K_w} \quad \text{Eq. S10}$$

Consequently, we obtain Eq. S11 where the logarithm of the global formation constant of water is equal to the co-logarithm of the autoprotolysis constant, both at the same value of temperature and ionic strength.

$$\log \beta_{1,1}^{OH^-|H^+} = pK_w \quad \text{Eq. S11}$$

## Appendix B

Table S1. Table of equivalence between salinity and ionic strength, expressed in mol L<sup>-1</sup>, for selected temperature values.

| Salinity [PSU] | Temperature [°C] |          |          |          |          |          |          |          |          |          |          |          |          |          |

In Fig. S1, the response surface is shown, establishing the relationship between salinity and ionic strength values in the defined temperature range. It is observed that the surface exhibits a slight curvature at extremely high and low salinity and ionic strength ranges, indicating that salinity and ionic strength do not vary proportionally under these conditions.

**Fig. S1.** QR code for the response surface for the equivalence between salinity and ionic strength values for the proposed temperature range.

## Appendix C

### Determination of pH through the solution of a third-degree polynomial

This polynomial allows the determination of  $[H^+]$  in a solution prepared either from the acid, an alkaline metal salt of the conjugate base, or both. Its derivation is described in the following steps.

First, the apparent acidity constant of the conjugate pair  $HA/A^-$  associated with the equilibrium  $HA \rightleftharpoons H^+ + A^-$ , where  $HA$  represents a generic acidic species, and  $A^-$  represents its respective conjugate base, is considered (Eq. S12).

$$K_a = \frac{1}{\beta_{1,1}^{A^-|H^+}} = \frac{[H^+][A^-]}{[HA]} \quad \text{Eq. S12}$$

Next, the apparent constant for water formation,  $H^+ + OH^- \rightleftharpoons H_2O$  (Eq. S13), where  $K_w$  is the apparent constant for the autoprotolysis of water, is considered. For simplicity, this work prefers the notation  $[H^+]$  instead of  $[H_3O^+]$  to denote the effective molar concentration of hydronium ions. This equilibrium is obtained by removing one water molecule from each side of the equality defining  $K_w$ .

$$\beta_{1,1}^{OH^-|H^+} = \frac{1}{[H^+][OH^-]} = \frac{1}{K_w} \quad \text{Eq. S13}$$

Note that the origin of the conjugate base may also be due to the presence of a strong electrolyte, such as a potassium salt. In such a case, Eq. S14 can be established based on the equilibrium of solution formation,  $KA \rightarrow K^+ + A^-$ .

$$C_{KA} = [K^+] \quad \text{Eq. S14}$$

In the case of a solution where both the acid and the conjugate base are present, equilibrium Eq. S15, can be established, which is valid regardless of the origin of the acidic species and the alkaline species.

$$C_{\text{buffer}} = [HA] + [A^-] \quad \text{Eq. S15}$$

The charge balance (or, according to some texts, the principle of electroneutrality on a solution) postulates that a solution is electrically neutral. Mathematically, it is shown by an expression where the sum of the effective molar concentrations of the cations, each one multiplied by the absolute value of their charge, is equal to the sum of the effective molar concentrations of the anions, each one multiplied by the absolute value of its charge (Castellan, 1983; Burgot, 2012; Butler, 1998). Thus, the charge balance is fulfilled regardless of the origin of the chemical species. This relationship is represented in Eq. S16, where the  $i$ -th cationic species and the  $j$ -th anionic species are represented.

$$\sum |z_i| [i^{z^+}] = \sum |z_j| [j^{z^-}] \quad \text{Eq. S16}$$

Thus, Eq. S17 presents the charge balance of a solution of a potassium salt of a conjugate base (KA) that exhibits the behavior of a true electrolyte, accompanied by the acidic particle and the basic particle of the water. In the presence of any true univalent electrolyte used to fix ionic strength, and whose constituent ions are chemically inert, these ions will appear on both sides of the equation, resulting in no net contribution to the charge balance.

$$[A^-] + [OH^-] = [H^+] + [K^+] \quad \text{Eq. S17}$$

First, the effective molar concentration of the conjugate base,  $[A^-]$ , is determined from Eq. S17 and the molar concentration of the alkaline metal,  $[K^+]$ , is replaced with the analytical concentration of Eq. S14.

$$[A^-] = C_{KA} + [H^+] - [OH^-] \quad \text{Eq. S18}$$

On the other hand,  $[HA]$  is determined from Eq. S15 and the term  $[A^-]$  is replaced with the calculation presented in Eq. S18.

$$[HA] = C_{\text{buffer}} - [A^-] \quad \text{Eq. S19}$$

$$[HA] = (C_{HA} + C_{KA}) - (C_{KA} + [H^+] - [OH^-])$$

This results in Eq. S20.

$$[HA] = C_{HA} - [H^+] + [OH^-] \quad \text{Eq. S20}$$

Then, the expression for the law of mass action of the acidity constant for the conjugate pair HA/A<sup>-</sup> (Eq. S12) is taken, and  $[H^+]$  is determined.

$$[H^+] = K_a \frac{[HA]}{[A^-]} \quad \text{Eq. S21}$$

The numerator (Eq. S20) and the denominator (Eq. S18) are identifiable, and they are then substituted into Eq. S21.

$$[H^+] = K_a \frac{(C_{HA} - [H^+] + [OH^-])}{(C_{KA} + [H^+] - [OH^-])} \quad \text{Eq. S22}$$

The  $[OH^-]$  is determined from Eq. S13 to express Eq. S22 solely in terms of  $[H^+]$ , the initial

concentration of the acid,  $C_{HA}$ , the initial concentration of the base,  $C_{KA}$ , and the apparent acidity constant.

$$[H^+] = K_a \frac{\left( C_{HA} - [H^+] + \frac{K_w}{[H^+]} \right)}{\left( [H^+] - \frac{K_w}{[H^+]} \right)} \quad \text{Eq. S23}$$

From Eq. S23 two cases arise. The first, when the solution is prepared solely from the acid,  $C_{HA} = C_0$ , and consequently,  $C_{KA} = 0 \text{ mol L}^{-1}$ , resulting in Eq. S24.

$$[H^+] = K_a \frac{\left( C_{HA} - [H^+] + \frac{K_w}{[H^+]} \right)}{\left( [H^+] - \frac{K_w}{[H^+]} \right)} \quad \text{Eq. S24}$$

The linear version of the above expression is a third-degree polynomial (Eq. S25) whose positive root satisfying the condition  $[H^+] \in \mathbb{R}^+$  is linked to the pH value.

$$[H^+]^3 + K_a[H^+]^2 + (-K_w - K_a C_0)[H^+] - K_a K_w = 0 \quad \text{Eq. S25}$$

The second case arises when the solution is prepared solely from a salt of an alkaline metal of the conjugate base,  $C_{KA} = C_0$ , and consequently,  $C_{HA} = 0 \text{ mol L}^{-1}$ . Eq. S26 is obtained.

$$[H^+] = K_a \frac{\left( -[H^+] + \frac{K_w}{[H^+]} \right)}{\left( C_{KA} + [H^+] - \frac{K_w}{[H^+]} \right)} \quad \text{Eq. S26}$$

The linear version of the above expression is the other third-degree polynomial (Eq. S27) whose positive root satisfying the condition  $[H^+] \in \mathbb{R}^+$  is again linked to the pH value.

$$[H^+]^3 + (K_a + C_0)[H^+]^2 - K_w[H^+] - K_a K_w = 0 \quad \text{Eq. S27}$$

In either case, Eq. S28 is satisfied, making the value of the logarithm of the apparent formation constant applicable, in terms of  $K_a$ , in the above expressions.

$$\log \left( \beta_{1,1}^{A^-|H^+} \Big|_{I>0} \right) = pK_a(H^+/A^-) \Big|_{I>0} \quad \text{Eq. S28}$$

## Appendix D

### Relative percentage differences calculated for $\Delta_r H^\circ$ and $\Delta_r S^\circ$

**Table S2.** Comparison of the thermodynamic parameters for the equilibrium  $H^+ + OH^- \rightleftharpoons H_2O$  obtained by the proposed non-linear fit in this work and the reported values. The relative difference (%) is added only as a plain comparison criterion.
